

public class `java.math`

BigInteger

English

Read

[Hide details](#) [Login](#)Java SE 6 [RSS](#)**Extends:** `Number`**Implements:** `Comparable`

Immutable arbitrary-precision integers. All operations behave as if `BigInteger`s were represented in two's-complement notation (like Java's primitive integer types). `BigInteger` provides analogues to all of Java's primitive integer operators, and all relevant methods from `java.lang.Math`. Additionally, `BigInteger` provides operations for modular arithmetic, GCD calculation, primality testing, prime generation, bit manipulation, and a few other miscellaneous operations.

Semantics of arithmetic operations exactly mimic those of Java's integer arithmetic operators, as defined in *The Java Language Specification*. For example, division by zero throws an `ArithmeticException`, and division of a negative by a positive yields a negative (or zero) remainder. All of the details in the Spec concerning overflow are ignored, as `BigInteger`s are made as large as necessary to accommodate the results of an operation.

Semantics of shift operations extend those of Java's shift operators to allow for negative shift distances. A right-shift with a negative shift distance results in a left shift, and vice-versa. The unsigned right shift operator (`>>>`) is omitted, as this operation makes little sense in combination with the "infinite word size" abstraction provided by this class.

Semantics of bitwise logical operations exactly mimic those of Java's bitwise integer operators. The binary operators (`and`, `or`, `xor`) implicitly perform sign extension on the shorter of the two operands prior to performing the operation.

Comparison operations perform signed integer comparisons, analogous to those performed by Java's relational and equality operators.

Modular arithmetic operations are provided to compute residues, perform exponentiation, and compute multiplicative inverses. These methods always return a non-negative result, between 0 and $(\text{modulus} - 1)$, inclusive.

Bit operations operate on a single bit of the two's-complement representation of their operand. If necessary, the operand is sign-extended so that it contains the designated bit. None of the single-bit

operations can produce a BigInteger with a different sign from the BigInteger being operated on, as they affect only a single bit, and the "infinite word size" abstraction provided by this class ensures that there are infinitely many "virtual sign bits" preceding each BigInteger.

For the sake of brevity and clarity, pseudo-code is used throughout the descriptions of BigInteger methods. The pseudo-code expression $(i + j)$ is shorthand for "a BigInteger whose value is that of the BigInteger i plus that of the BigInteger j ." The pseudo-code expression $(i == j)$ is shorthand for "true if and only if the BigInteger i represents the same value as the BigInteger j ." Other pseudo-code expressions are interpreted similarly.

All methods and constructors in this class throw `NullPointerException` when passed a null object reference for any input parameter.

version 1.75, 06/28/06
since JDK1.1
See also [java.math.BigDecimal](#)

Fields	
final public static BigInteger	ZERO The BigInteger constant zero. since 1.2
final public static BigInteger	ONE The BigInteger constant one. since 1.2
final public static BigInteger	TEN The BigInteger constant ten. since 1.5

Constructors	
public	BigInteger (byte[] val) Translates a byte array containing the two's-complement binary representation of a BigInteger into a BigInteger. The input array is assumed to be in <i>big-endian</i> byte-order: the most significant byte is in the zeroth element. <i>val</i> big-endian two's-complement binary representation of BigInteger. Throws NumberFormatException : val is zero bytes long.
public	BigInteger (int signum, byte[] magnitude) Translates the sign-magnitude representation of a BigInteger into a BigInteger. The sign is represented as an integer signum

	<p>value: -1 for negative, 0 for zero, or 1 for positive. The magnitude is a byte array in <i>big-endian</i> byte-order: the most significant byte is in the zeroth element. A zero-length magnitude array is permissible, and will result in a BigInteger value of 0, whether signum is -1, 0 or 1.</p> <p><i>signum</i> signum of the number (-1 for negative, 0 for zero, 1 for positive).</p> <p><i>magnitude</i> big-endian binary representation of the magnitude of the number.</p> <p>Throws NumberFormatException: <i>signum</i> is not one of the three legal values (-1, 0, and 1), or <i>signum</i> is 0 and <i>magnitude</i> contains one or more non-zero bytes.</p>
public	<p>BigInteger(String val, int radix)</p> <p>Translates the String representation of a BigInteger in the specified radix into a BigInteger. The String representation consists of an optional minus sign followed by a sequence of one or more digits in the specified radix. The character-to-digit mapping is provided by <code>Character.digit</code>. The String may not contain any extraneous characters (whitespace, for example).</p> <p><i>val</i> String representation of BigInteger.</p> <p><i>radix</i> radix to be used in interpreting <i>val</i>.</p> <p>Throws NumberFormatException: <i>val</i> is not a valid representation of a BigInteger in the specified radix, or <i>radix</i> is outside the range from <code>Character#MIN_RADIX</code> to <code>Character#MAX_RADIX</code>, inclusive.</p> <p>See also <code>digit</code></p>
public	<p>BigInteger(String val)</p> <p>Translates the decimal String representation of a BigInteger into a BigInteger. The String representation consists of an optional minus sign followed by a sequence of one or more decimal digits. The character-to-digit mapping is provided by <code>Character.digit</code>. The String may not contain any extraneous characters (whitespace, for example).</p> <p><i>val</i> decimal String representation of BigInteger.</p> <p>Throws NumberFormatException: <i>val</i> is not a valid representation of a BigInteger.</p> <p>See also <code>digit</code></p>
public	<p>BigInteger(int numBits, Random rnd)</p> <p>Constructs a randomly generated BigInteger, uniformly distributed over the range 0 to $(2^{\text{numBits}} - 1)$, inclusive. The uniformity of the distribution assumes that a fair source of random bits is provided in <i>rnd</i>. Note that this constructor</p>

	<p>always constructs a non-negative BigInteger.</p> <p><i>numBits</i> maximum bitLength of the new BigInteger.</p> <p><i>rnd</i> source of randomness to be used in computing the new BigInteger.</p> <p>Throws <code>IllegalArgumentException</code>: <i>numBits</i> is negative.</p> <p>See also bitLength()</p>
public	<p>BigInteger(int bitLength, int certainty, <code>Random</code> rnd)</p> <p>Constructs a randomly generated positive BigInteger that is probably prime, with the specified bitLength.</p> <p>It is recommended that the <code>probablePrime</code> method be used in preference to this constructor unless there is a compelling need to specify a certainty.</p> <p><i>bitLength</i> bitLength of the returned BigInteger.</p> <p><i>certainty</i> a measure of the uncertainty that the caller is willing to tolerate. The probability that the new BigInteger represents a prime number will exceed $(1 - 1/2^{\text{certainty}})$. The execution time of this constructor is proportional to the value of this parameter.</p> <p><i>rnd</i> source of random bits used to select candidates to be tested for primality.</p> <p>Throws <code>ArithmeticException</code>: <i>bitLength</i> < 2.</p> <p>See also bitLength()</p>

Methods

public <code>BigInteger</code>	<p>abs()</p> <p>Returns a BigInteger whose value is the absolute value of this BigInteger.</p> <p>return <code>abs(this)</code></p>
public <code>BigInteger</code>	<p>add(<code>BigInteger</code> val)</p> <p>Returns a BigInteger whose value is <code>(this + val)</code>.</p> <p><i>val</i> value to be added to this BigInteger.</p> <p>return <code>this + val</code></p>
public <code>BigInteger</code>	<p>and(<code>BigInteger</code> val)</p> <p>Returns a BigInteger whose value is <code>(this & val)</code>. (This method returns a negative BigInteger if and only if this and val are both negative.)</p> <p><i>val</i> value to be AND'ed with this BigInteger.</p> <p>return <code>this & val</code></p>

public BigInteger	andNot(BigInteger val) Returns a BigInteger whose value is $(this \& \sim val)$. This method, which is equivalent to <code>and(val.not())</code> , is provided as a convenience for masking operations. (This method returns a negative BigInteger if and only if <code>this</code> is negative and <code>val</code> is positive.) <i>val</i> value to be complemented and AND'ed with this BigInteger. return <code>this & ~val</code>
public int	bitCount() Returns the number of bits in the two's complement representation of this BigInteger that differ from its sign bit. This method is useful when implementing bit-vector style sets atop BigIntegers. return number of bits in the two's complement representation of this BigInteger that differ from its sign bit.
public int	bitLength() Returns the number of bits in the minimal two's-complement representation of this BigInteger, <i>excluding</i> a sign bit. For positive BigIntegers, this is equivalent to the number of bits in the ordinary binary representation. (Computes $(\text{ceil}(\log_2(\text{this} < 0 ? -\text{this} : \text{this}+1)))$.) return number of bits in the minimal two's-complement representation of this BigInteger, <i>excluding</i> a sign bit.
public BigInteger	clearBit(int n) Returns a BigInteger whose value is equivalent to this BigInteger with the designated bit cleared. (Computes $(\text{this} \& \sim(1 \ll n))$.) <i>n</i> index of bit to clear. return <code>this & ~(1<<n)</code> Throws ArithmeticException : <i>n</i> is negative.
public int	compareTo(BigInteger val) Compares this BigInteger with the specified BigInteger. This method is provided in preference to individual methods for each of the six boolean comparison operators (<code><</code> , <code>==</code> , <code>></code> , <code>>=</code> , <code>!=</code> , <code><=</code>). The suggested idiom for performing these comparisons is: <code>(x.compareTo(y) <op> 0)</code> , where <code><op></code> is one of the six comparison operators. <i>val</i> BigInteger to which this BigInteger is to be compared. return -1, 0 or 1 as this BigInteger is numerically less than, equal to, or greater than <code>val</code> .

public BigInteger	divide(BigInteger val) Returns a BigInteger whose value is $(this / val)$. <i>val</i> value by which this BigInteger is to be divided. return $this / val$ Throws ArithmeticException : $val == 0$
public BigInteger[]	divideAndRemainder(BigInteger val) Returns an array of two BigIntegers containing $(this / val)$ followed by $(this \% val)$. <i>val</i> value by which this BigInteger is to be divided, and the remainder computed. return an array of two BigIntegers: the quotient $(this / val)$ is the initial element, and the remainder $(this \% val)$ is the final element. Throws ArithmeticException : $val == 0$
public double	doubleValue() Converts this BigInteger to a double. This conversion is similar to the <i>narrowing primitive conversion</i> from double to float defined in the Java Language Specification : if this BigInteger has too great a magnitude to represent as a double, it will be converted to <code>Double#NEGATIVE_INFINITY</code> or <code>Double#POSITIVE_INFINITY</code> as appropriate. Note that even when the return value is finite, this conversion can lose information about the precision of the BigInteger value. return this BigInteger converted to a double.
public boolean	equals(Object x) Compares this BigInteger with the specified Object for equality. <i>x</i> Object to which this BigInteger is to be compared. return true if and only if the specified Object is a BigInteger whose value is numerically equal to this BigInteger.
public BigInteger	flipBit(int n) Returns a BigInteger whose value is equivalent to this BigInteger with the designated bit flipped. (Computes $(this \wedge (1 \ll n))$.) <i>n</i> index of bit to flip. return $this \wedge (1 \ll n)$ Throws ArithmeticException : n is negative.
public float	floatValue() Converts this BigInteger to a float. This conversion is similar to the <i>narrowing primitive conversion</i> from double to float defined in the Java Language Specification : if this BigInteger has too great a magnitude to represent as a float, it will be converted to <code>Float#NEGATIVE_INFINITY</code> or

	<p><code>Float#POSITIVE_INFINITY</code> as appropriate. Note that even when the return value is finite, this conversion can lose information about the precision of the <code>BigInteger</code> value.</p> <p>return this <code>BigInteger</code> converted to a <code>float</code>.</p>
public <code>BigInteger</code>	<p>gcd(<code>BigInteger</code> val)</p> <p>Returns a <code>BigInteger</code> whose value is the greatest common divisor of <code>abs(this)</code> and <code>abs(val)</code>. Returns 0 if <code>this==0 && val==0</code>.</p> <p><i>val</i> value with which the GCD is to be computed.</p> <p>return <code>GCD(abs(this), abs(val))</code></p>
public int	<p>hashCode()</p> <p>Returns the hash code for this <code>BigInteger</code>.</p> <p>return hash code for this <code>BigInteger</code>.</p>
public int	<p>intValue()</p> <p>Converts this <code>BigInteger</code> to an <code>int</code>. This conversion is analogous to a <i>narrowing primitive conversion</i> from <code>long</code> to <code>int</code> as defined in the Java Language Specification: if this <code>BigInteger</code> is too big to fit in an <code>int</code>, only the low-order 32 bits are returned. Note that this conversion can lose information about the overall magnitude of the <code>BigInteger</code> value as well as return a result with the opposite sign.</p> <p>return this <code>BigInteger</code> converted to an <code>int</code>.</p>
public long	<p>longValue()</p> <p>Converts this <code>BigInteger</code> to a <code>long</code>. This conversion is analogous to a <i>narrowing primitive conversion</i> from <code>long</code> to <code>int</code> as defined in the Java Language Specification: if this <code>BigInteger</code> is too big to fit in a <code>long</code>, only the low-order 64 bits are returned. Note that this conversion can lose information about the overall magnitude of the <code>BigInteger</code> value as well as return a result with the opposite sign.</p> <p>return this <code>BigInteger</code> converted to a <code>long</code>.</p>
public <code>BigInteger</code>	<p>max(<code>BigInteger</code> val)</p> <p>Returns the maximum of this <code>BigInteger</code> and <code>val</code>.</p> <p><i>val</i> value with which the maximum is to be computed.</p> <p>return the <code>BigInteger</code> whose value is the greater of this and <code>val</code>. If they are equal, either may be returned.</p>
public <code>BigInteger</code>	<p>min(<code>BigInteger</code> val)</p> <p>Returns the minimum of this <code>BigInteger</code> and <code>val</code>.</p> <p><i>val</i> value with which the minimum is to be computed.</p>

	<p>return the BigInteger whose value is the lesser of this BigInteger and <code>val</code>. If they are equal, either may be returned.</p>
public BigInteger	<p>mod(BigInteger <code>m</code>) Returns a BigInteger whose value is $(\text{this} \bmod m)$. This method differs from <code>remainder</code> in that it always returns a <i>non-negative</i> BigInteger.</p> <p><code>m</code> the modulus.</p> <p>return <code>this mod m</code></p> <p>Throws ArithmeticException: <code>m <= 0</code></p> <p>See also <code>remainder</code></p>
public BigInteger	<p>modInverse(BigInteger <code>m</code>) Returns a BigInteger whose value is $(\text{this}^{-1} \bmod m)$.</p> <p><code>m</code> the modulus.</p> <p>return <code>this⁻¹ mod m</code>.</p> <p>Throws ArithmeticException: <code>m <= 0</code>, or this BigInteger has no multiplicative inverse mod <code>m</code> (that is, this BigInteger is not <i>relatively prime</i> to <code>m</code>).</p>
public BigInteger	<p>modPow(BigInteger <code>exponent</code>, BigInteger <code>m</code>) Returns a BigInteger whose value is $(\text{this}^{\text{exponent}} \bmod m)$. (Unlike <code>pow</code>, this method permits negative exponents.)</p> <p><code>exponent</code> the exponent.</p> <p><code>m</code> the modulus.</p> <p>return <code>this^{exponent} mod m</code></p> <p>Throws ArithmeticException: <code>m <= 0</code></p> <p>See also <code>modInverse</code></p>
public BigInteger	<p>multiply(BigInteger <code>val</code>) Returns a BigInteger whose value is $(\text{this} * \text{val})$.</p> <p><code>val</code> value to be multiplied by this BigInteger.</p> <p>return <code>this * val</code></p>
public BigInteger	<p>negate() Returns a BigInteger whose value is $(-\text{this})$.</p> <p>return <code>-this</code></p>
public BigInteger	<p>nextProbablePrime() Returns the first integer greater than this BigInteger that is probably prime. The probability that the number returned by this method is composite does not exceed 2^{-100}. This method will never skip over a prime when searching: if it returns <code>p</code>, there is no prime <code>q</code> such that <code>this < q < p</code>.</p> <p>return the first integer greater than this BigInteger that is probably prime.</p> <p>Throws ArithmeticException: <code>this < 0</code>.</p>

	since 1.5
public BigInteger	not() Returns a BigInteger whose value is $(\sim\text{this})$. (This method returns a negative value if and only if this BigInteger is non-negative.) return $\sim\text{this}$
public BigInteger	or(BigInteger val) Returns a BigInteger whose value is $(\text{this} \mid \text{val})$. (This method returns a negative BigInteger if and only if either this or val is negative.) <i>val</i> value to be OR'ed with this BigInteger. return $\text{this} \mid \text{val}$
public BigInteger	pow(int exponent) Returns a BigInteger whose value is $(\text{this}^{\text{exponent}})$. Note that exponent is an integer rather than a BigInteger. <i>exponent</i> exponent to which this BigInteger is to be raised. return $\text{this}^{\text{exponent}}$ Throws ArithmeticException : exponent is negative. (This would cause the operation to yield a non-integer value.)
public static BigInteger	probablePrime(int bitLength, Random rnd) Returns a positive BigInteger that is probably prime, with the specified bitLength. The probability that a BigInteger returned by this method is composite does not exceed 2^{-100} . <i>bitLength</i> bitLength of the returned BigInteger. <i>rnd</i> source of random bits used to select candidates to be tested for primality. return a BigInteger of bitLength bits that is probably prime Throws ArithmeticException : bitLength < 2. since 1.4 See also bitLength()
public BigInteger	remainder(BigInteger val) Returns a BigInteger whose value is $(\text{this} \% \text{val})$. <i>val</i> value by which this BigInteger is to be divided, and the remainder computed. return $\text{this} \% \text{val}$ Throws ArithmeticException : val==0
public BigInteger	shiftLeft(int n) Returns a BigInteger whose value is $(\text{this} \ll n)$. The shift distance, n, may be negative, in which case this method performs a right shift. (Computes $\text{floor}(\text{this} * 2^n)$.)

	<p><i>n</i> shift distance, in bits.</p> <p>return this << n</p> <p>See also shiftRight</p>
public BigInteger	<p>shiftRight(int n) Returns a BigInteger whose value is (this >> n). Sign extension is performed. The shift distance, n, may be negative, in which case this method performs a left shift. (Computes floor(this / 2ⁿ).)</p> <p><i>n</i> shift distance, in bits.</p> <p>return this >> n</p> <p>See also shiftLeft</p>
public int	<p>signum() Returns the signum function of this BigInteger.</p> <p>return -1, 0 or 1 as the value of this BigInteger is negative, zero or positive.</p>
public BigInteger	<p>subtract(BigInteger val) Returns a BigInteger whose value is (this - val).</p> <p><i>val</i> value to be subtracted from this BigInteger.</p> <p>return this - val</p>
public boolean	<p>testBit(int n) Returns true if and only if the designated bit is set. (Computes ((this & (1<<n)) != 0).)</p> <p><i>n</i> index of bit to test.</p> <p>return true if and only if the designated bit is set.</p> <p>Throws ArithmeticException: n is negative.</p>
public byte[]	<p>toByteArray() Returns a byte array containing the two's-complement representation of this BigInteger. The byte array will be in <i>big-endian</i> byte-order: the most significant byte is in the zeroth element. The array will contain the minimum number of bytes required to represent this BigInteger, including at least one sign bit, which is (ceil((this.bitLength() + 1)/8)). (This representation is compatible with the (byte[]) constructor.)</p> <p>return a byte array containing the two's-complement representation of this BigInteger.</p> <p>See also BigInteger(byte[])</p>
public String	<p>toString(int radix) Returns the String representation of this BigInteger in the given radix. If the radix is outside the range from Character#MIN_RADIX to Character#MAX_RADIX inclusive, it will default to 10 (as is the case for Integer.toString). The digit-to-character mapping provided by Character.forDigit is used,</p>

	<p>and a minus sign is prepended if appropriate. (This representation is compatible with the <code>(String, int)</code> constructor.)</p> <p><i>radix</i> radix of the String representation.</p> <p>return String representation of this BigInteger in the given radix.</p> <p>See also <code>toString</code>, <code>forDigit</code>, <code>BigInteger(java.lang.String, int)</code></p>
public String	<p>toString()</p> <p>Returns the decimal String representation of this BigInteger. The digit-to-character mapping provided by <code>Character.forDigit</code> is used, and a minus sign is prepended if appropriate. (This representation is compatible with the <code>(String)</code> constructor, and allows for String concatenation with Java's <code>+</code> operator.)</p> <p>return decimal String representation of this BigInteger.</p> <p>See also <code>forDigit</code>, <code>BigInteger(java.lang.String)</code></p>
public static BigInteger	<p>valueOf(long val)</p> <p>Returns a BigInteger whose value is equal to that of the specified <code>long</code>. This "static factory method" is provided in preference to a <code>(long)</code> constructor because it allows for reuse of frequently used BigIntegers.</p> <p><i>val</i> value of the BigInteger to return.</p> <p>return a BigInteger with the specified value.</p>
public BigInteger	<p>xor(BigInteger val)</p> <p>Returns a BigInteger whose value is <code>(this ^ val)</code>. (This method returns a negative BigInteger if and only if exactly one of this and <code>val</code> are negative.)</p> <p><i>val</i> value to be XOR'ed with this BigInteger.</p> <p>return <code>this ^ val</code></p>

Properties

public BigInteger	<p>setBit(int n)</p> <p>Returns a BigInteger whose value is equivalent to this BigInteger with the designated bit set. (Computes <code>(this (1<<n))</code>.)</p> <p><i>n</i> index of bit to set.</p> <p>return <code>this (1<<n)</code></p> <p>Throws <code>ArithmeticException</code>: <code>n</code> is negative.</p>
public int	<p>getLowestSetBit()</p> <p>Returns the index of the rightmost (lowest-order) one bit in this BigInteger (the number of zero bits to the right of the rightmost</p>

	<p>one bit). Returns -1 if this BigInteger contains no one bits. (Computes $(this == 0 ? -1 : \log_2(this \& -this))$.)</p> <p>return index of the rightmost one bit in this BigInteger.</p>
public boolean	<p>isProbablePrime(int certainty)</p> <p>Returns <code>true</code> if this BigInteger is probably prime, <code>false</code> if it's definitely composite. If <code>certainty</code> is ≤ 0, <code>true</code> is returned.</p> <p><i>certainty</i> a measure of the uncertainty that the caller is willing to tolerate: if the call returns <code>true</code> the probability that this BigInteger is prime exceeds $(1 - 1/2^{\text{certainty}})$. The execution time of this method is proportional to the value of this parameter.</p> <p>return <code>true</code> if this BigInteger is probably prime, <code>false</code> if it's definitely composite.</p>
